

## Some Answers on: Undecidability

G1: (a) Suppose we can decide if two PDAs accept the same language. Then on input PDA  $M$ , build a simple PDA  $N$  that accepts all strings of that alphabet. Then test whether  $M$  and  $N$  accept the same strings. This answers the question of whether  $M$  accepts all strings. Which contradicts what is known.

(b) Take  $N$  and convert to Chomsky Normal Form. Create all strings in increasing order of length, checking each to see if generated by  $N$ . Stop and accept if find a string *not* generated by  $N$ .

(c) No.

G2: (a) False. ( $S_{tm}$  is not even r.e.)

(b) True. (Since FAs are guaranteed to halt, we can simulate them.)

(c) True. (Since a program can be represented by a finite string.)

(d) True.

G3: Assume that  $L$  is recursive (but neither empty nor  $\Sigma^*$ ). Then  $L$  is accepted by some TM  $M$  that always halts. Let  $x$  be any string in  $L$ , let  $y$  be any string in  $\bar{L}$ . Then the reduction is: “On input  $w$ , run  $M$  on  $w$ . If  $M$  accepts  $w$  then output  $y$ , else output  $x$ .”

Assume that  $L$  is the language of TM  $M$  and that  $L$  reduces to  $\bar{L}$  by reduction  $f$ . Then the decider for  $L$  is: “On input  $w$ , calculate  $f(w)$ . Run  $M$  on both  $w$  and  $f(w)$  in parallel. If  $M$  accepts  $w$  then accept; if  $M$  accepts  $f(w)$  then reject.” This works, since if  $w \in L$ , then  $M$  will halt and accept  $w$ ; and if  $w \notin L$ , then  $f(w) \in \bar{L}$ , so  $M$  will halt and accept  $f(w)$ .

G4: (a) Acceptance problem for TM.

(b) Does not exist.

(c) The integers

(d) The real numbers

(e)  $0^n 1^n 2^n$
